# Stochastic Pi-Calculus Revisited 

Luca Cardelli ${ }^{1}$, Radu Mardare ${ }^{2 \star}$<br>${ }^{1}$ Microsoft Research, Cambridge, UK<br>${ }^{2}$ Aalborg University, Denmark

#### Abstract

We develop a version of stochastic Pi-calculus with a semantics based on measure theory. We define the behaviour of a process in a rate environment using measures over the measurable space of processes induced by structural congruence. We extend the stochastic bisimulation to include the concept of rate environment and prove that this equivalence is a congruence which extends the structural congruence.

## 1 Introduction

The problem of specifying and analyzing nondeterministic concurrent systems has found a successful solution in the class of Process Algebras (PAs) [2]. The compositionality of the processes is reflected by the construction principles of PAs, while their behaviours are transition systems. As a result, one obtains a class of processes with an elegant algebraic-coalgebraic structure, supported by appealing theories and easy to adapt to various modelling requirements.

The same approach has been taken for probabilistic and stochastic concurrent systems. Probabilistic process algebras [2], interactive Markov chain algebra [16, 4] and stochastic process algebras (SPA) such as TIPP [13], PEPA [14, 15], EMPA [3] and stochastic Pi-calculus [22] are extensions of classic PAs. The nondeterminism is replaced by a race policy and this requires important modifications in the semantic format. Stressed to mimic the pointwise structural operational semantics (SOS) of nondeterministic PAs, SPAs find ad hoc solutions to the problems introduced by stochasticity, such as the multi-transition system approach of PEPA or the proved $S O S$ approach of stochastic Pi-calculus. These result in complex constructs that are difficult to extend to a general format for well-behaved stochastic specifications and problematic when recursion or fresh name quantification are considered. As emphasized by Klin and sassone in [17], for stochastic Pi-calculus of Priami [22] the parallel composition fails to be associative up to bisimulation, while for PEPA, if arbitrary relations between the rates of processes and subprocesses are allowed, stochastic bisimulation ceases to be a congruence. An explanation for these situations is given in [17]: the information carried by the aforementioned SOS frameworks is excessive, while a well-behaved framework should only carry the exact amount of data required for the derivation of the intended semantics.

[^0]These problems motivate our research, initiated with [7], that aims to reconsider the semantics of SPAs from a perspective faithful to the algebraiccoalgebraic structure of stochastic processes. The key observation is that structural congruence induces a $\sigma$-algebra on processes and organizes a measurable space of stochastic processes. We propose a semantics that assign to each process a set of measures indexed by observable actions. Thus, difficult instance-counting problems that otherwise require complicated versions of SOS can be solved by exploiting the properties of measures (e.g. additivity). Our previous work showed that along this line one obtains an elegant semantics that resembles the one of nondeterministic PAs and provides a well-behaved notion of bisimulation. In previous work [7] we proved this concept for a fragment of stochastic CCS. In this paper we extend the work to stochastic Pi-calculus with channel-based communication, mobility, fresh name quantification and replication. This calculus is designed to satisfy the specific requirements of Systems Biology.

There are several novel ideas in our approach. The processes are interpreted in stochastic environments that associate basic rates to channels. In a rate environment $E$, a process $P$ has associated a class of measures $\mu$, written $E \vdash P \rightarrow \mu$. For each action $\alpha, \mu(\alpha)$ is a measure over the space of processes; $\mu(\alpha)(S) \in \mathbb{Q}^{+}$is the rate of an exponentially distributed random variable that characterizes the $\alpha$-transitions from $P$ to (elements of) a measurable set $S$. Only the structural congruence-closed sets are measurable. This is essential for modelling in systems biology, where such sets represent chemical soups ${ }^{1}$. This choice provides simple solutions to the problems of replications and bound outputs which otherwise, as with Milner's Abstraction-Concretion method [20], require complicated highorder reasoning. Also novel is our stochastic bisimulation that extends other similar ones $[19,17,7,21,8]$ by making explicit the role of the rate environments. We show that bisimulation is a congruence that extends structural congruence.

Related works. The idea of transitions from states to measures has been advocated in the context of probabilistic automata [18, 24] and Markov processes [21]. The transition-systems-as-coalgebras paradigm [10,23] exploits it providing a uniform characterisation of transition systems that covers the sequence nondeterministic, probabilistic and stochastic systems. A general SOS format for SPAs without new name operators or recursion is proposed in [17]. In [8, 9] these ideas are applied to particular SPAs with pointwise semantics. With respect to these works, in our paper we consider a different measurable space that not only answers to practical modelling requirements, but also simplifies the semantics and gives us smooth solutions for the fresh name quantification and replication without requiring additional constructs. Formally, while the other frameworks focus on the monads freely generated by the algebraic signature of the calculus, we have considered the equational monad defined by the structural congruence. The use of name environments has been considered in [11, 12] where it involves the machinery of nominal sets. We have tried to avoid this together with any coalgebraic description of the lifting from processes to measures, as our intention

[^1]is to make these ideas accessible also for the readers less familiar with the jargon of Category Theory.

Relation to Nondeterministic Pi-Calculus. There is no trivial relation between nondeterministic Pi-calculus and our stochastic Pi-calculus, in the sense that one cannot simply recover the semantics of the other by simple mathematical transformations. This is because the measure-based semantics of stochastic-Pi calculus require important modification of the SOS rules. One example regards the replication: while in classic Pi -calculus $!a(b) \equiv a(b) \mid!a(b)$, in stochastic Pi this is illegal since the rate of the input on channel $a$ in the process $a(b) \mid!a(b)$ is strictly bigger than the rate of the same input in the process $!a(b)$. For this reason in stochastic Pi there exist no structural congruence rules of type $!P \equiv P \mid!P$ or $!!P \equiv!P$ since such rules would generate processes with infinite rates; instead, there are dedicated SOS rules that establish the correct behaviours.

## 2 Preliminaries

In this section we introduce the terminology and the notations used in the paper.
For the sets $A$ and $B, 2^{A}$ denotes the powerset of $A$ and $B^{A}$ the class of functions from $A$ to $B$. For an equivalence relation $\sim$ on $A, A^{\sim}$ is the set of equivalence classes and $a^{\sim}$ the equivalence class of $a \in A$.

Given a set $M, \Sigma \subseteq 2^{M}$ that contains the element $M$ and is closed under complement and countable union is a $\sigma$-algebra over $M ;(M, \Sigma)$ is a measurable space and the elements of $\Sigma$ are measurable sets.

A measure on $(M, \Sigma)$ is a countably additive set function $\mu: \Sigma \rightarrow \mathbb{R}^{+}$such that $\mu(\emptyset)=0$. The null measure $\mathbb{O}$ is such that $\mathbb{O}(M)=0$. For $N \in \Sigma$, the $N$-Dirac measure $D_{N}$ is defined by $D_{N}\left(N^{\prime}\right)=1$, if $N \subseteq N^{\prime}$ and $D_{N}\left(N^{\prime}\right)=0$ otherwise. $\Delta(M, \Sigma)$ denotes the set of measures on $(M, \Sigma)$.

If $\mathfrak{R} \subseteq M \times M, N \subseteq M$ is $\mathfrak{R}$-closed iff $\{m \in M \mid \exists n \in N,(n, m) \in \mathfrak{R}\} \subseteq N$. If $(M, \Sigma)$ is a measurable space, $\Sigma(\mathfrak{R})$ is the set of measurable $\mathfrak{R}$-closed sets.

## 3 Stochastic Pi-Calculus

In this section we introduce a version of stochastic Pi-calculus equipped with an early semantics [2] expressed in terms of measure theory. Being developed mainly for applications in Systems Biology, this calculus is designed to respect the chemical kinetics (the Chemical Master Equation) [5] which provides the mathematical principles for calculating the rates of the channel-based communications. The class $\mathbb{P}$ of processes is endowed with structural congruence which generates a $\sigma$-algebra $\Pi$ on $\mathbb{P}$. In addition, rate environments assign base rates to channel names. The behaviour of a process $P$ in a rate environment $E$ is defined by an indexed set of measures $\mu: \mathbb{A}^{+} \rightarrow \Delta(\mathbb{P}, \Pi)$, where $\mathbb{A}^{+}$is the set of actions.

### 3.1 Syntax

Definition 1 (Processes). Let $\mathcal{N}$ be a countable set. The stochastic processes are defined, on top of 0 , for arbitrary $r \in \mathbb{Q}^{+}$and $a, b, c \in \mathcal{N}$, as follows.

$$
P:=0 \vdots x \cdot P \vdots(a @ r) P \vdots P \mid P \vdots P+P \vdots!P, \quad x:=a(b) \vdots a[b]
$$

Let $\mathbb{P}$ be the set of stochastic processes. 0 stands for the inactive process. An input " $a(b)$ " is the capability of the process $a(b) . P$ to receive a name on channel $a$ that replaces $b$ in all its occurrences inside $P$. An output prefix " $a[b]$ " represents the action of sending a name $b$ on channel $a$. " $(a @ r)$ " is the fresh name operator that, unlike in nondeterministic PAs, also specifies the rate $r$ of the fresh name. As usual in Pi-calculus, we have the parallel composition "|", the choice operator "+" and the replication operator "!".

For arbitrary $P \in \mathbb{P}$, we define the set $f n(P)$ of the free names of $P$ inductively by $f n(0)=\emptyset, f n(a(b) . P)=(f n(P) \backslash\{b\}) \cup\{a\}, f n(a[b] . P)=f n(P) \cup\{a, b\}$, $f n(P \mid Q)=f n(P+Q)=f n(P) \cup f n(Q), f n((a @ r) P)=f n(P) \backslash\{a\}$ and $f n(!P)=$ $f n(P)$. As usual in process algebras, for arbitrary $a, b \in \mathcal{N}$, we write $P_{\{a / b\}}$ for the process term obtained from $P$ by substituting all the free occurrences of $b$ with $a$, renaming as necessary to avoid capture.

Definition 2 (Structural congruence). Structural congruence is the smallest equivalence relation $\equiv \subseteq \mathbb{P} \times \mathbb{P}$ satisfying the following conditions.
$\boldsymbol{I} .(\mathbb{P}, \mid, 0)$ is a commutative monoid for $\equiv$, i.e.,

1. $P|Q \equiv Q| P ; \quad 2 .(P \mid Q)|R \equiv P|(Q \mid R) ; \quad 3 . P \mid 0 \equiv P$.
II. $(\mathbb{P},+, 0)$ is a commutative monoid for $\equiv$, i.e.,
2. $P+Q \equiv Q+P$;
3. $(P+Q)+R \equiv P+(Q+R)$;
4. $P+0 \equiv P$.
III. $\equiv$ is a congruence for the algebraic structure of $\mathbb{P}$, i.e., if $P \equiv Q$, then
5. $P|R \equiv Q| R$;
6. $P+R \equiv Q+R$;
7. $!P \equiv!Q$;
8. $a[b] . P \equiv a[b] . Q$
9. $(a @ r) P \equiv(a @ r) Q$;
10. $a(b) \cdot P \equiv a(b) \cdot Q$.
IV. the fresh name quantifiers satisfy the following conditions
11. if $a \neq b$, then $(a @ r)(b @ s) P \equiv(b @ s)(a @ r) P ; \quad 2 .(a @ r) 0 \equiv 0$;
12. if $a \notin f n(P)$, then $(a @ r)(P \mid Q) \equiv P \mid(a @ r) Q$ and $(a @ r)(P+Q) \equiv P+(a @ r) Q$.
$\boldsymbol{V}$. the replication satisfies the following conditions
$1 .!0 \equiv 0 ; \quad 2 .!(P \mid Q) \equiv!P \mid!Q$.
$\boldsymbol{V I} . \equiv$ satisfies the alpha-conversion rules
13. $(a @ r) P \equiv(b @ r) P_{\{b / a\}} ; \quad$ 2. $a(b) P \equiv a(c) P_{\{c / b\}}$.

If $Q$ is obtained from $P$ by alpha-conversion (VI) 1-2, we write $P \equiv{ }^{*} Q$. Let $\Pi$ be the set of the $\equiv$-closed subsets of $\mathbb{P}$. Note that $\mathbb{P} \equiv$ is a countable partition of $\mathbb{P}$ and $\Pi$ is the $\sigma$-algebra generated by $\mathbb{P} \equiv$.

Notice that, unlike in the nondeterministic case, we do not have $!!P \equiv!P$ nor $!P \equiv P \mid!P$. These are not sound due to the rate competition which else will generate processes with infinite rates.

Theorem 1 (Measurable space). $(\mathbb{P}, \Pi)$ is a measurable space of processes.

The measurable sets of $\mathbb{P}$ are the unions of $\equiv$-equivalence classes on $\mathbb{P}$. In what follows $\mathcal{P}, \mathcal{R}, \mathcal{Q}$ range over $\Pi$. We lift some functions and algebraic operations from processes to measurable sets, for arbitrary $a, b \in \mathcal{N}$ and $r \in \mathbb{Q}^{+}$, as follows.

$$
\begin{gathered}
f n(\mathcal{P})=\bigcup_{P \in \mathcal{P}} f n(P), \quad \mathcal{P}_{\{a / b\}}=\bigcup_{P \in \mathcal{P}} P_{\{a / b\}}, \quad \mathcal{P} \mid \mathcal{Q}=\bigcup_{P \in \mathcal{P}}^{Q \in \mathcal{Q}}(P \mid Q)^{\equiv}, \\
\mathcal{P}_{\mathcal{Q}}=\bigcup_{R \mid Q \in \mathcal{P}}^{Q \in \mathcal{Q}} R^{\equiv}, \quad(a @ r) \mathcal{P}=\bigcup_{P \in \mathcal{P}}(a @ r) P^{\equiv}
\end{gathered}
$$

It is not difficult to see that these operations are internal operations on $\Pi$.

### 3.2 Rate environments

Now we introduce rate environments used to interpret stochastic processes. They are partial functions on $\mathcal{N}$ assigning rates to channels. We chose to introduce them in the "process algebra style" instead of defining a type systems for environment correctness, which would complicate the semantics.

Definition 3 (Rate Environment). The rate environments associated to $\mathcal{N}$ are defined, on top of a constant $\varepsilon$, for arbitrary $a \in \mathcal{N}$ and $r \in \mathbb{Q}^{+}$, by

$$
E:=\varepsilon \vdots E, a @ r .
$$

Let $\mathbb{E}$ be the set of rate environments. A suffix $a @ r$ is called rate declaration. If $a @ r$ appears in $E$, we write $a @ r \in E . \varepsilon$ stands for the empty environment. We treat "," as concatenation symbol for rate environments and use " $E, E^{\prime \prime}$ " to denote the concatenation of $E$ and $E^{\prime} ; \varepsilon$ is the empty symbol for concatenation.

For $E=E_{1}, \ldots, E_{n} \in \mathbb{E}$ and $\{1, . ., n\}=\left\{i_{1}, . ., i_{k}\right\} \cup\left\{j_{1}, . ., j_{n-k}\right\}$ with $i_{1}<$ $\ldots<i_{k}, j_{1}<\ldots<j_{n-k}$, if $E^{\prime}=E_{i_{1}}, . ., E_{i_{k}}$ and $E^{\prime \prime}=E_{j_{1}}, . ., E_{j_{n-k}}$, we write $E^{\prime} \subset E$ and $E^{\prime \prime}=E \backslash E^{\prime}$. Notice that $\varepsilon \subset E, E \subset E, E=E \backslash \varepsilon$ and $\varepsilon=E \backslash E$. The domain of a rate environment is the partial function on $\mathbb{E}$ defined as follows.

1. $\operatorname{dom}(\varepsilon)=\emptyset$;
2. if $\operatorname{dom}(E)$ is defined and $a \notin \operatorname{dom}(E)$, then $\operatorname{dom}(E, a @ r)=\operatorname{dom}(E) \cup\{a\}$;
3. undefined otherwise.

In what follows, whenever we use $\operatorname{dom}(E)$ we implicitly assume that $\operatorname{dom}$ is defined in $E$. Observe that, if $a \in \operatorname{dom}(E)$, then there exists a rate declaration $a @ r \in E$ and for no $s \neq r, a @ s \in E$; for this reason we also write $r=E(a)$. When $\operatorname{dom}(E)$ is defined, let $\operatorname{dom}(E)^{*}=\{a \in \operatorname{dom}(E)$ s.t. $E(a) \neq 0\}$.

### 3.3 The class of indexed measures

The semantics will involve terms of type $E \vdash P \rightarrow \mu$, where $E$ is a rate environment, $P$ is a process and $\mu: \mathbb{A}^{+} \rightarrow \Delta(\mathbb{P}, \Pi)$ is a mapping that defines a set of labeled measures. The labels are the observable actions collected in the set $\mathbb{A}^{+}$ defined below.

$$
\mathbb{A}=\left\{a[b], a[@ r], a b, \quad \text { for } a, b \in \mathcal{N}, r \in \mathbb{Q}^{+}\right\} \text {and } \mathbb{A}^{+}=\mathbb{A} \cup\{\tau\}
$$

We denote by $\mathfrak{M}$ the set $\Delta(\mathbb{P}, \Pi)^{\mathbb{A}^{+}}$of labeled measures.

The observable actions consist of four classes: (i) free outputs of type $a[b]$ denoting the action of sending a free name $b$ over the channel $a$, (ii) bound outputs of type $a[@ r]$ denoting the action of sending a fresh unspecified name, with base-rate $r$, on channel $a$, (iii) input actions of type $a b$ representing the fact that channel $a$ has received a name $b$ (as the result of an output action on $a$ ), (iv) internal action $\tau$ - communications. In what follows we use $\alpha, \alpha_{i}$ to represent arbitrary elements of $\mathbb{A}^{+}$.

Notice the relation between the syntactic prefixes of the calculus and the observable actions. The output prefixes, as in Pi-calculus, represent observable output actions. The input prefix of the calculus, such as $a(b)$ in the process $a(b) . P$, does not represent an authentic action, but the capability of $P$ to receive a name on channel $a$; consequently we adopt an early semantics [2]: if a name $c$ is sent on $a$, the input action is $a c$ and it labels the transitions to $P_{\{c / b\}}$. In this way, to a single prefix $a(b)$ correspond as many input actions $a c$ as names $c$ can be sent on $a$ in the given rate-environment. Unlike the nondeterministic case, for stochastic Pi-calculus we cannot define a late semantics [2] because only the input actions of type $a c$ correspond to a measure on the space of processes, while $a(b)$ represents a set of measures, one for each name received. Because our semantics aims to associate a measure to each process and action label, we need to refuse the inputs of type $a(b)$ in the set of labels and chose an early semantics.

The bound output $a[@ r]$ in the form that ignores the argument of communication is novel. It labels a bound output of type ( $b @ r$ ) a $b] . P$. The example below explains its action; anticipating the semantics, $E \vdash P \xrightarrow{\alpha, r} Q \equiv$ means that in the environment $E, P$ can do an $\alpha$-transition with rate $r$ to the elements of $Q^{\equiv}$.

Example 1. The processes $Q=(b @ r) a[b] \cdot P$ and $R=(c @ r) a[c] \cdot P_{\{c / b\}}$ are structural congruent and we want them bisimilar in our semantics. If we consider that the (only) observable transition in which $Q$ can be involved is $a[b @ r]$, as it is done in other PAs, then the transition is $E \vdash(b @ r) a[b] . P \xrightarrow{a[b @ r], E(a)}(b @ r) P^{\equiv}$, while for $R$ the transition is $E \vdash(c @ r) a[c] \cdot P_{\{c / b\}} \xrightarrow{a[c @ r], E(a)}(c @ r) P_{\{c / b\}}^{\bar{\equiv}}$. Obviously, $(b @ r) P^{\equiv}=(c @ r) P_{\{c / b\}}^{\overline{\bar{n}}}$, but if $b \neq c$, then $a[b @ r] \neq a[c @ r]$ and in effect, $Q$ and $R$ are not bisimilar in this interpretation.

For obtaining the expected bisimulations, for any $b, c \in \mathcal{N}, a[b @ r]=a[c @ r]$; and this is equivalent with accepting that an external observer can only see that a private name with the base rate $r$ has been sent on channel $a$ without seeing the name. Hence, the real observable action has to be $a[@ r]$.

Our solution is similar to the Abstraction-Concretion method proposed in [20] for nondeterministic Pi-calculus. $a[@ r]$ does the job of Abstraction, as our measurable sets of processes are Milner's abstracted processes. Only that in our case, because the transitions are not between processes but from processes to structural-congruence classes, we need no Concretions. So, the main advantage of our approach is that it solves the problem of bound outputs without using higher order syntax as in the classic Pi-calculus.

Before proceeding with the operational semantics, we need to define a set of operations on $\mathfrak{M}$ that lift the process constructors of stochastic Pi-calculus to the
level of the labeled distributions over the space of processes. These operations reflect the complexity of the normal forms of the $\tau$-reductions for stochastic Pi and for this reason the reader is invited to study Definition 4 in the context of the operational semantics presented in the next section. The SOS rules clarify and prove the correctness of these operations.

Let $\mathbb{A}_{@}$ denote the set $\left\{a[@ r]\right.$, for $\left.a \in \mathcal{N}, r \in \mathbb{Q}^{+}\right\}$of bound output actions and $\mathbb{A}_{a}$ denotes the set $\left\{a[b], a b, a[@ r]\right.$, for $\left.b \in \mathcal{N}, r \in \mathbb{Q}^{+}\right\}$of actions on channel $a$. A labeled measure $\mu \in \mathfrak{M}$ has finite support if the set of output actions $\alpha \in \mathbb{A}^{+}$ with $\mu(\alpha) \neq \mathbb{O}$ is finite or empty. Recall that © denotes the null measure and $D_{P \equiv}$ the $P^{\equiv}$-Dirac measure.

Definition 4. Consider the following operations on $\mathfrak{M}$ defined for arbitrary $\mu, \eta \in \mathfrak{M}, E \in \mathbb{E}, \alpha \in \mathbb{A}^{+}, a, b, c \in \mathcal{N}, P \in \mathbb{P}$ and $\mathcal{P}, \mathcal{Q}, \mathcal{R} \in \Pi$.

1. Operations of arity 0 .
(i) Let $\overline{\mathbb{O}} \in \mathfrak{M}$ defined by $\overline{\mathbb{O}}(\alpha)=\mathbb{0}$ for any $\alpha \in \mathbb{A}^{+}$;
(ii) Let $E_{P \equiv}^{a[b]}, E_{P \equiv}^{a(b)} \in \mathfrak{M}$ defined whenever $f n(P) \subseteq \operatorname{dom}(E)$, by $E_{P \equiv}^{a[b]}(a[b])=E(a) D_{P \equiv \text { and } E_{P \equiv}^{a[b]}(\alpha)=\mathbb{0} \text {, for } \alpha \neq a[b] ; ~}^{\text {; }}$ $E_{P \equiv}^{a(b)}(a c)=E(a) D_{P_{\{c / b\}} \overline{c_{2}}}$ and $E_{P \equiv}^{a(b)}(\alpha)=\mathbb{0}$, for $\alpha \neq a c$.
2. Operations of arity 1.
(i) Let $\mu_{\mathcal{P}} \in \mathcal{M}$ defined by $\mu_{\mathcal{P}}(\alpha)(\mathcal{R})=\mu(\alpha)\left(\mathcal{R}_{\mathcal{P}}\right)$.
(ii) Let $(a @ r) \mu \in \mathcal{M}$ defined by

$$
(a @ r) \mu(\alpha)(\mathcal{R})= \begin{cases}\mu(\alpha)(\mathcal{P}), & \text { if } \alpha \notin \mathbb{A}_{a} \cup \mathbb{A}_{@}, \mathcal{R}=(a @ r) \mathcal{P} \\ \mu(b[a])(\mathcal{P})+\mu(b[@ r])(\mathcal{P}), & \text { if } \alpha=b[@ r], \mathcal{R}=(a @ r) \mathcal{P} \\ 0, & \text { otherwise }\end{cases}
$$

3. Operations of arity 2.
(i) Let $\mu \oplus \eta \in \mathcal{M}$, defined by $(\mu \oplus \eta)(\alpha)=\mu(\alpha)+\eta(\alpha)$.
(ii) For $\mu, \eta \in \mathfrak{M}$ with finite support, let $\mu \mathcal{p}^{\otimes}{ }_{\mathcal{Q}}^{E} \eta \in \mathcal{M}$ defined by - for $\alpha \in \mathbb{A}, \quad\left(\mu \mathcal{P} \otimes_{\mathcal{Q}}^{E} \eta\right)(\alpha)(\mathcal{R})=\mu_{\mathcal{Q}}(\alpha)(\mathcal{R})+\eta_{\mathcal{P}}(\alpha)(\mathcal{R})$;

- for $\tau, \quad\left(\mu \mathcal{P}_{\mathcal{Q}_{\mathcal{Q}}}^{E} \eta\right)(\tau)(\mathcal{R})=\mu_{\mathcal{Q}}(\tau)(\mathcal{R})+\eta_{\mathcal{P}}(\tau)(\mathcal{R})+$

$$
\begin{aligned}
& \sum_{\mathcal{P}_{1} \mid \mathcal{P}_{2} \subseteq \mathcal{R}}^{\substack{a \in \operatorname{dom(E)^{*}} \\
b \in \mathcal{N}}} \frac{\mu(a[b])\left(\mathcal{P}_{1}\right) \cdot \eta(a b)\left(\mathcal{P}_{2}\right)+\eta(a[b])\left(\mathcal{P}_{1}\right) \cdot \mu(a b)\left(\mathcal{P}_{2}\right)}{E(a)}+ \\
& \left((x @ r) y[x] \cdot P^{\prime} \mid P^{\prime \prime}\right)+P^{\prime \prime \prime} \equiv \subseteq \mathcal{P} \\
& \sum_{(x @ r)\left(P^{\prime} \mid Q_{\{x / z\}}^{\prime}\right)\left|P^{\prime \prime}\right| Q^{\prime \prime} \equiv \subseteq \mathcal{R}}^{\left(y(z) \cdot Q^{\prime} \mid Q^{\prime \prime}\right)+Q^{\prime \prime \prime} \subseteq \mathcal{Q}} \frac{\mu(y[@ r])\left((x @ r) P^{\prime} \mid P^{\prime \prime \equiv}\right) \cdot \eta(y x)\left(Q_{\{x / z\}}^{\prime} \mid Q^{\prime \prime \equiv}\right)}{E(a)}+ \\
& \sum_{(x @ r)\left(P_{\{x / z\}}^{\prime} \mid Q^{\prime}\right)\left|P^{\prime \prime}\right| Q^{\prime \prime} \equiv \subseteq \mathcal{R}}^{\substack{\left(y(z) \cdot P^{\prime} \mid P^{\prime \prime}\right)+P^{\prime \prime \prime} \equiv \subseteq \mathcal{P} \\
\left((x @ r) y[x] \cdot Q^{\prime} \mid Q^{\prime \prime}\right)+Q^{\prime \prime \prime} \equiv \subseteq \mathcal{P}}} \frac{\mu(y x)\left(P_{\{x / z\}}^{\prime} \mid P^{\prime \prime \equiv}\right) \cdot \eta(y[@ r])\left((x @ r) Q^{\prime} \mid Q^{\prime \prime \equiv}\right)}{E(a)}
\end{aligned}
$$

Observe that because we work with functions with finite support and because $\operatorname{dom}(E)$ is defined and finite, the sums involved in the definition of $\mu \mathcal{p} \otimes_{\mathcal{Q}}^{E} \eta$ have finite numbers of non-zero summands. These operations are the building blocks for the lifting of the algebraic structure of processes to the level of functions: operations of arity 0 encode process 0 and prefixing, operations of arity 1 encode the quotient and fresh name quantification and operations of arity 2 correspond to choice and parallel composition. For understanding their role, the reader is referred to the semantic rules introduce in the next section.

Lemma 1. 1. For $\mu, \eta, \rho \in \mathfrak{M}$ it holds that $\mu \oplus \eta \in \mathfrak{M}$ and
$(a) . \mu \oplus \eta=\eta \oplus \mu, \quad(b) .(\mu \oplus \eta) \oplus \rho=\mu \oplus(\eta \oplus \rho), \quad(c) \cdot \mu=\mu \oplus \overline{\mathbb{D}}$.
2. For $\mu, \eta, \rho \in \mathfrak{M}$ with finite support, $\mu \mathcal{P} \otimes_{\mathcal{Q}}^{E} \eta \in \mathfrak{M}$ and
(a). $\mu \mathcal{\mathcal { P }} \otimes_{\mathcal{Q}}^{E} \eta=\eta \mathcal{Q}_{\mathcal{\mathcal { P }}}^{E} \mu, \quad(b) .\left(\mu \mathcal{P} \otimes_{\mathcal{Q}}^{E} \eta\right) \mathcal{P} \mid \mathcal{Q}^{\otimes_{\mathcal{R}}} \rho^{E}=\mu \mathcal{P} \otimes_{\mathcal{Q} \mid \mathcal{R}}^{E}\left(\eta \mathcal{Q}_{\mathcal{R}}^{E} \rho\right)$,
(c). $\mu \mathcal{P} \otimes_{0}^{E} \overline{\mathbb{O}}=\mu$.

### 3.4 Semantics

The stochastic transition relation is the smallest relation $\mathfrak{T} \subseteq \mathbb{E} \times \mathbb{P} \times \mathfrak{M}$ satisfying the semantics rules listed below, where $E \vdash P \rightarrow \mu$ denotes $(E, P, \mu) \in \mathfrak{T}$; it states that the behaviour of $P$ in the environment $E$ is defined by the mapping $\mu \in \mathfrak{M}$. For each $\equiv$-closed set of processes $\mathcal{P} \in \Pi$ and each $\alpha \in \mathbb{A}^{+}, \mu(\alpha)(\mathcal{P}) \in$ $\mathbb{Q}^{+}$represents the total rate of the $\alpha$-reductions of $P$ to the elements of $\mathcal{P}$. The rules involve also predicates of type $E \vdash o k$ that encode the correctness of $E$, i.e. that the environment associates base rates to a finite number of channels only, and that no channel appears in more than one rate declaration in that environment. Recall that $\equiv^{*}$ denotes alpha-conversion.
$(E n v \varepsilon) . \overline{\varepsilon \vdash o k}$
$(E n v @) \cdot \frac{E \vdash o k \quad a \notin \operatorname{dom}(E)}{E, a @ r \vdash o k}$
$(N u l l) . \frac{E \vdash o k}{E \vdash 0 \rightarrow \overline{\mathbb{O}}}$
$(O u t) . \quad \frac{E \vdash o k \quad f n(a[b] \cdot P) \subseteq \operatorname{dom}(E)}{E \vdash a[b] \cdot P \rightarrow E_{P}^{a[b]}}$
(Sum). $\frac{E \vdash P \rightarrow \mu \quad E \vdash Q \rightarrow \eta}{E \vdash P+Q \rightarrow \mu \oplus \eta}$
$(I m p) . \frac{E \vdash o k \quad f n(a(b) . P) \subseteq \operatorname{dom}(E)}{E \vdash a(b) \cdot P \rightarrow E_{P \equiv}^{a(b)}}$
(New). $\frac{E, a @ r \vdash P \rightarrow \mu}{E \vdash(a @ r) P \rightarrow(a @ r) \mu} \quad$ (Par). $\frac{E \vdash P \rightarrow \mu \quad E \vdash Q \rightarrow \eta}{E \vdash P \mid Q \rightarrow \mu_{P \equiv} \otimes_{Q}^{E} \equiv \eta}$
(Alpha). $\frac{E \vdash P \rightarrow \mu \quad P \equiv^{*} Q}{E \vdash Q \rightarrow \mu} \quad$ (Rep). $\frac{E \vdash P \rightarrow \mu}{E \vdash!P \rightarrow \mu!P \equiv}$
( Null ) guarantees that in any correct environment the behaviour of process 0 is described by $\overline{0}$, which associates the rate 0 to any transition.
(Out) and (Imp) have similar actions. They associates to any prefixed process $x . P$, where $x \in\{a(b), a[b] \mid a, b \in \mathcal{N}\}$, the mapping $E_{P \equiv}^{x}$ which, as described in Definition 4, associates the base-rate of the channel of $x$ to the $x$-transitions from $x . P$ to $P^{\equiv}$ and rate 0 to the other transitions.
(Sum) computes the rate of the $\alpha$-transitions from $P+Q$ to $\mathcal{R} \in \Pi$, as the sum of the rates of the $\alpha$-transitions from $P$ and $Q$ to $\mathcal{R}$ respectively.
(Par) describes the possible interactions between the processes. If $\rho=\mu_{P} \otimes_{Q}{ }_{Q} \equiv$ $\eta$, the rate $\rho(\alpha)(\mathcal{R})$ of the $\alpha$-transitions from $P \mid Q$ to $\mathcal{R}$ for $\alpha \neq \tau$, is the sum of the rates $\mu(\alpha)\left(\mathcal{R}_{Q} \equiv\right)$ and $\eta(\alpha)\left(\mathcal{R}_{P} \equiv\right)$ of the $\alpha$-transitions from $P$ to $\mathcal{R}_{Q}$ and from $Q$ to $\mathcal{R}_{P}$ respectively; the rate of the $\tau$-transitions from $P \mid Q$ to $\mathcal{R}$ is the sum of the rates of the $\tau$-transitions that $P$ or $Q$ can do independently plus the rate of all communications between $P$ and $Q$ (bound represented by the first sum in Definition 4 3.(ii) and unbound represented by the last two sums). Because we use the base rate of the channel $a$ when we calculate the rates of both inputs and outputs on $a$, the sums in Definition 4 3.(ii) are normalised by $E(a)$.
(New) establishes that the rate of the transitions from $(a @ r) P$ to $(a @ r) \mathcal{R} \in$ $\Pi$ in the environment $E$ is the rate of the corresponding transitions from $P$ to $\mathcal{R}$ in the environment $E, a @ r$. The only thing one needs to take care of (see Definition 4) is when an output becomes bound while (New) is used. Consider, for instance, the process $Q=b[a] \cdot P+(c @ r) b[c] \cdot P_{\{c / a\}}$.

$$
E, a @ r \vdash Q \xrightarrow{b[a], E(b)} P^{\equiv} \text { and } E, a @ r \vdash Q \xrightarrow{b[@ r], E(b)}(c @ r) P_{\{c / a\}}^{\overline{\bar{~}}} .
$$

Now, if we consider $(a @ r) Q \equiv(a @ r) b[a] . P+(c @ r) b[c] \cdot P_{\{c / a\}}$, because $(a @ r) P \equiv$ $(c @ r) P_{\{c / a\}}$, the rates of the transitions in the environment $E$ should be
$E \vdash(a @ r) Q \xrightarrow{b[a], 0}(a @ r) P^{\equiv}$ and $E \vdash(a @ r) Q \xrightarrow{b[@ r], 2 E(b)}(a @ r) P^{\equiv}$.
Notice that the rate of $b[a]$-transition of $Q$ contributes to the rate of $b[@ r]$ transition of $(a @ r) Q$ and this is how Definition 4 introduces $(a @ r) \mu$.
(Rep) encodes the intuition that in the case of stochastic systems, if $E \vdash P \xrightarrow{\alpha, r} Q^{\equiv}$, then $E \vdash!P \xrightarrow{\alpha, r}!P \mid Q^{\equiv}$.
(Alpha) proves properties by alpha-conversion: it guarantees that the behaviour of a process does not change if the bound variables are renamed. The standard presentations of PAs with unlabeled reduction mix structural congruence with reductions by rules of type (Struct). Because our reductions are labeled (the labels are hidden into the mappings), alpha conversion needs to be separately incorporated both in the algebra and coalgebra.

The next example illustrates some transitions in our framework.

Example 2. $E \vdash(b @ r)(a[b] \cdot P) \mid a(c) \cdot Q \xrightarrow{\tau, E(a)}(b @ r)\left(P \mid Q_{\{b / c\}}\right) \equiv$.
From (Out) or (Imp) we derive $E, b @ r \vdash a[b] . P \xrightarrow{a[b], E(a)} P \equiv$. (New) gives us further that $E \vdash(b @ r) a[b] \cdot P \xrightarrow{a[@ r], E(a)}(b @ r) P \equiv$ and this is the only transition with non-zero rate. Observe that the definition of $E_{Q}^{a(c)}$ implies $E \vdash a(c) \cdot Q \xrightarrow{a b, E(a)}$ $Q \overline{\overline{\bar{j}} / c\}}$.

Applying the definition of $(b @ r)(a[b] \cdot P) \equiv \otimes_{a(c) \cdot Q \equiv}^{E}$, we obtain
$E \vdash(b @ r)(a[b] \cdot P) \mid a(c) \cdot Q \xrightarrow{\tau, s}(b @ r)\left(P \mid Q_{\{b / c\}}\right) \equiv$ for $s=E(a)$ if $E(a) \neq 0$ and $s=0$ if $E(a)=0$.

A consequence of this result is the well known case of communication of a private name used for a private communication
$E \vdash(b @ r)(a[b] \cdot b(e) \cdot P) \mid a(c) \cdot c[d] \cdot 0 \xrightarrow{\tau, E(a)}(b @ r)(b(e) \cdot P \mid b[d] .0) \equiv \xrightarrow{\tau, r}(b @ r) P_{\{d / e\}}^{\overline{\bar{E}}}$. The first transition is a particular case of the example. For the second transition we apply the case 3 (ii) of Definition 4.

Remark 1. In stochastic Pi calculus it is not possible to define a binary operator on $\mathfrak{M}$ that reflects, for a fixed environment $E$, the parallel composition of processes. Assume that there exists an operator $\otimes^{E}$ such that if $E \vdash P \rightarrow \mu$ and $E \vdash Q \rightarrow \eta$, then $E \vdash P \mid Q \rightarrow \mu \otimes^{E} \eta$. The processes $P=a[b] .0 \mid c[d] .0$ and $Q=a[b] . c[d] .0+c[d] . a[b] .0$ have associated, in any correct environment $E$, the same mapping $\mu \in \mathfrak{M}$. Suppose that $E \vdash R \rightarrow \eta$, where $R=e[f] .0$. If, indeed, the operator $\otimes^{E}$ is well defined, then $E \vdash P \mid R \rightarrow \mu \otimes^{E} \eta$ and $E \vdash Q \mid R \rightarrow \mu \otimes^{E} \eta$, i.e. $P \mid R$ and $Q \mid R$ have associated the same mapping. But this is not the case, because $P^{\equiv} \neq Q^{\equiv}$ and

$$
\begin{aligned}
& E \vdash P \mid R \xrightarrow{e[f], E(e)} P \equiv \text { and } E \vdash P \mid R \xrightarrow{e[f], 0} Q^{\equiv} \text {, while } \\
& E \vdash Q \mid R \xrightarrow{e[f], 0} P \equiv \text { and } E \vdash Q \mid R \xrightarrow{e[f], E(e)} Q^{\equiv} .
\end{aligned}
$$

This explains why we need to index $\otimes^{E}$ with $P^{\equiv}$ and $Q^{\equiv}$ and why the algebraic signature is changed when the structure of processes is lifted to indexed measures.

The next theorem states that $\mathfrak{T}$ is well defined and characterizes the correctness of an environment.

Theorem 2. (i) If $E \vdash$ ok and $f n(P) \subseteq \operatorname{dom}(E)$, then there exists a unique $\mu \in \mathfrak{M}$ such that $E \vdash P \rightarrow \mu$.
(ii) If $E \vdash P \rightarrow \mu$, then $E \vdash o k$. Moreover, $E \vdash$ ok iff $E \vdash 0 \rightarrow \overline{\mathbb{0}}$.

Unlike in other process algebras, our semantics does not contain a (Struct) rule stating that structural congruent processes behave identicaly. However, such a result can be proved.

Theorem 3. If $E \vdash P^{\prime} \rightarrow \mu$ and $P^{\prime} \equiv P^{\prime \prime}$, then $E \vdash P^{\prime \prime} \rightarrow \mu$.
The next lemma describes how the environments can vary without influencing the mapping associated to a process.

Lemma 2. 1. If for any $a \in \mathcal{N}$ and $r \in \mathbb{Q},\left[a @ r \in E\right.$ iff $\left.a @ r \in E^{\prime}\right]$, then $E \vdash P \rightarrow \mu$ iff $E^{\prime} \vdash P \rightarrow \mu$.
2. If $E^{\prime} \vdash o k, E \subset E^{\prime}$ and $E \vdash P \rightarrow \mu$, then $E^{\prime} \vdash P \rightarrow \mu$.
3. If $E \subset E^{\prime}, E \vdash P \rightarrow \mu$ and $\operatorname{dom}\left(E^{\prime} \backslash E\right) \cap f n(P)=\emptyset$, then $E^{\prime} \vdash P \rightarrow \mu$.

## 4 Stochastic bisimulation

In this section we focus on stochastic bisimulation that reproduces, at the stochastic level, Larsen-Skou probabilistic bisimulation [19]. We have introduced a similar concept in [7] for the case of stochastic CCS. The novelty with the present definition consists in the role of the rate environments: two processes are stochastic bisimilar if they have similar stochastic behaviours in any rate environment.

Definition 5 (Stochastic Bisimulation). A rate-bisimulation on $\mathbb{P}$ is an equivalence relation $\mathfrak{R} \subseteq \mathbb{P} \times \mathbb{P}$ such that $(P, Q) \in \mathfrak{R}$ iff for any $E \in \mathbb{E}$,

- if $E \vdash P \rightarrow \mu$, then there exists $\eta \in \mathfrak{M}$ such that $E \vdash Q \rightarrow \eta$ and for any $C \in \Pi(\Re)$ and $\alpha \in \mathbb{A}^{+}, \mu(\alpha)(C)=\eta(\alpha)(C)$.
- if $E \vdash Q \rightarrow \eta$, then there exists $\mu \in \mathfrak{M}$ such that $E \vdash P \rightarrow \mu$ and for any $C \in \Pi(\mathfrak{R})$ and $\alpha \in \mathbb{A}^{+}, \eta(\alpha)(C)=\mu(\alpha)(C)$.

Two processes $P, Q \in \mathbb{P}$ are stochastic bisimilar, denoted $P \sim Q$, if there exists a rate-bisimulation connecting them.

Observe that stochastic bisimulation is the largest rate-bisimulation on $\mathbb{P}$.
Example 3. If $a, b, x, y \in \mathcal{N}, a \neq b$ and $x \notin f n(b[y] . Q)$, then

$$
a(x) \cdot P \mid b[y] \cdot Q \sim a(x) \cdot(P \mid b[y] \cdot Q)+b[y] \cdot(a(x) \cdot P \mid Q)
$$

Indeed, for any compatible rate environment $E$,

$$
E \vdash a(x) \cdot P \mid b[y] \cdot Q \rightarrow E_{P}^{a(x)}{ }_{a(x) \cdot P}^{\otimes_{b[y] \cdot Q} E_{Q}^{b[y]},}
$$

$$
E \vdash a(x) \cdot(P \mid b[y] \cdot Q)+b[y] \cdot(a(x) \cdot P \mid Q) \rightarrow E_{P \mid b[y] \cdot Q}^{a(x)} \oplus E_{a(x) \cdot P \mid Q}^{b[y]}
$$

and for arbitrary $C \in \Pi(\sim)$,

$$
E_{P}^{a(x)} \quad a(x) \cdot P=\otimes_{b[y] \cdot Q} E_{Q}^{b[y]}(\alpha)(C)=E_{P \mid b \cdot Q}^{a(x)} \oplus E_{a(x) \cdot P \mid Q}^{b[y]}(\alpha)(C)=
$$

The previous example shows bisimilar processes which are not structurally congruent. The reverse affirmation is not true.

Theorem 4. If $P \equiv Q$, then $P \sim Q$.
The next theorem, stating that stochastic bisimulation is a congruence, proves that we have identified a well-behaved semantics.

Theorem 5 (Congruence). If $P \sim Q$, then

1. for any $a, b \in \mathcal{N}, a(b) . P \sim a(b) . Q$ and $a[b] . P \sim a[b] . Q$;
2. for any $R \in \mathbb{P}, P+R \sim Q+R$,
3. for any $a \in \mathcal{N}$ and $r \in \mathbb{Q}^{+},(a @ r) P \sim(a @ r) Q$;
4. for any $R \in \mathbb{P}, P|R \sim Q| R$.
5. ! $P \sim!Q$.

## 5 Conclusions and future work

In this paper we have proposed a way of introducing stochastic process algebras that is faithful to the algebraic-coalgebraic structures of the concurrent Markovian processes. The semantics is given in terms of measure theory and describes
the lifting of the algebraic structure of processes to the level of measures on the measurable space of processes. The paper treats the case of the complete stochastic Pi-calculus. Instead of the discrete measurable space of processes, we consider the measurable space induced by structural congruence and this idea has important advantages. Firstly, it matches practical modelling requirements: the identity of a system is not given by the stochastic process used to model it, but by its structural-congruence class (for systems biology this represents a chemical soup). Secondly, by working with measures on this space, we get important advantages on the level of the underlying theory such as a simple and elegant semantics, simple solutions for the problems related to bound output and replication (that otherwise require complicate transition labeling and higher order reasoning) and a well-behaved notion of stochastic bisimulation including associativity. Other advantages derive from the use of the rate environments that guarantees a certain robustness in modelling: a model cab be easily refined by modifying its rate environment.

Our approach opens some future research directions. One is the study of the GSOS format where the main challenges are to understand the underlying category and the equational monad induced by structural congruence. Another is the definition of a pseudometric, similar with the one we introduce in [7], to measure the distance between processes in terms of similar behaviours. Our semantics is particularly appropriate for introducing such metrics via the metrics on measures such as the Kantorovich metrics on distributions used, for instance, in [21]. This SPA is also particularly appropriate for logical analysis using an equational-coequational logic as the one we propose in [6], which will allow a canonic characterization of the measurable space of processes.

## Appendix

In this appendix we have collected some of the proofs of the main results presented in the paper.

Proof (Theorem 2). (i) Firstly, we prove the existential part by induction on the structure of $P$.

For $P=0, P=a[b] \cdot Q$ and $P=a(b) \cdot Q$, (Null), (Out) and (Imp) respectively guarantee the existence of $\mu$.

For $P=Q+R$ : the inductive hypothesis proves that there exist two functions $\eta, \rho$ such that $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$. From (Sum) we obtain that there exists $\mu=\eta \oplus \rho$ such that $E \vdash P \rightarrow \mu$.

For $P=Q \mid R$ : the inductive hypothesis guarantees that there exist two functions $\eta, \rho$ such that $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$. From (Par) we obtain that

For $P=(a @ r) Q$ : if $a \notin \operatorname{dom}(E)$, then $E, a @ r \vdash o k$ and the inductive hypothesis guarantees the existence of $\eta$ such that $E, a @ r \vdash Q \rightarrow \eta$. Further, applying (New), we get $E \vdash P \rightarrow(a @ r) \eta$. If $a \in \operatorname{dom}(E)$, let $b \in \mathcal{N} \backslash \operatorname{dom}(E)$. Then $E, b @ r \vdash o k$ and the inductive hypothesis guarantees the existence of $\eta$ such that $E, b @ r \vdash Q_{\{b / a\}} \rightarrow \eta$. Further, applying (New), we get $E \vdash(b @ r) Q_{\{b / a\}} \rightarrow$ $(b @ r) \eta$ and (Alpha) gives $E \vdash(a @ r) Q \rightarrow(b @ r) \eta$.

For $P=!Q$ : the inductive hypothesis guarantees the existence of a unique $\eta$ such that $E \vdash Q \rightarrow \eta$, and using (Rep), $E \vdash P \rightarrow \eta_{!Q}$.

The uniqueness part is done by induction on derivations.
The rules (Enve) and (Env@) are only proving the correctness of environments and consequently will not interfere with our proof.

Observe that all the derivations involving only the rules (Sum), (Par), (New) and (Rep), called in what follows basic proofs, demonstrate properties about processes with a more complex syntax than the processes involved in the hypotheses. Consequently, taking (Null), (Out) and (Imp) as basic cases, an induction on the structures of the processes involved in the derivations shows the uniqueness of $\mu$ for the situation of the basic proofs. Notice, however, that due to (New) a basic proof proves properties of type $E \vdash P \rightarrow \mu$ only for cases when new $(P) \cap \operatorname{dom}(E)=\emptyset$, where $\operatorname{new}(P)$ is the set of names of $P$ bound by fresh name quantifiers. To conclude the proof we need to show that if $Q=P_{\{a / b\}}$ with $a, b \notin f n(P)$ and if $E \vdash P \rightarrow \mu$ and $E \vdash Q \rightarrow \eta$ can be proved with basic proofs, then $\mu=\eta$. We do this by induction on $P$.
If $P=0$, then $Q=0$ and $\eta=\mu=\overline{0}$.
If $P=c[d] . R$, then $Q=c[d] . R_{\{a / b\}}$ and $a, b \notin f n(R)$. Moreover, $\mu=E_{R \equiv}^{c[d]}$ and $\eta=E_{R=\{a / b\}}^{c[d]}$. But because $a, b \notin f n(R), R \equiv R_{\{a / b\}}$ implying further $\mu=\eta$.
If $P=c(d) \cdot R$, then if $d \neq b$ the proof goes as in the previous case. If $P=c(b) \cdot R$, then $Q=c(a) \cdot R_{\{a / b\}}, \mu=E_{R}^{c(b)}$ and $\eta=E_{R_{\{a / b\}}}^{c(a)}$ and $\mu=\eta$.
If $P=S+T$, then $Q=S_{\{a / b\}}+T_{\{a / b\}}$. Let $E \vdash S \rightarrow \rho$ and $E \vdash T \rightarrow \nu$, then $E \vdash S_{\{a / b\}} \rightarrow \rho$ and $E \vdash T_{\{a / b\}} \rightarrow \nu$. Hence, $\mu=\eta=\rho \oplus \nu$.
If $P=S \mid T$ the proof goes as in the previous case.
If $P=!R, Q=!R_{\{a / b\}}$. Suppose that $E \vdash R \rightarrow \rho$. From the inductive hypothesis we also obtain that $E \vdash R_{\{a / b\}} \rightarrow \rho$. Because $a, b \notin f n(R),!R \equiv!R_{\{a / b\}}$.
If $P=(c @ r) R$ with $c \neq b$, then $Q=(c @ r) R_{\{a / b\}}$. Because we are in the case of a basic proof, $c \notin \operatorname{dom}(E)$. Suppose that $E, c @ r \vdash R \rightarrow \rho$. This is the unique hypothesis that proves $E \vdash P \rightarrow \mu$. Then, $\mu=(c @ r) \rho$ and the inductive hypothesis implies that $E, c @ r \vdash R_{\{a / b\}} \rightarrow \rho$ is the unique hypothesis that proves $E \vdash Q \rightarrow \eta$. Further, $E \vdash(c @ r) R_{\{a / b\}} \rightarrow(c @ r) \rho$ and $\mu=\eta$.
If $P=(b @ r) R$, then $Q=(a @ r) R_{\{a / b\}}$. Because we work with basic proofs, we have $a, b \notin \operatorname{dom}(E)$. A simple induction proves that if $E, b @ r \vdash R \rightarrow$ $\rho$, then $E, a @ r \vdash R_{\{a / b\}} \rightarrow \rho^{\prime}$, where for any $\alpha \in \mathbb{A}^{+}$and any $\mathcal{R} \in \Pi$, $\rho(\alpha)(\mathcal{R})=\rho^{\prime}\left(\alpha_{\{a / b\}}\right)\left(\mathcal{R}_{\{a / b\}}\right)$. From here we get $(b @ r) \rho=(a @ r) \rho^{\prime}$. Observe that $E, b @ r \vdash R \rightarrow \rho$ is the unique hypothesis that can be used in a basic proof to derive $E \vdash(b @ r) R \rightarrow \mu$ and $\mu=(b @ r) \rho$. Similarly, $E, a @ r \vdash R_{\{a / b\}} \rightarrow \rho^{\prime}$ is the unique hypothesis to prove $E \vdash(a @ r) R_{\{a / b\}} \rightarrow \eta$ and $\eta=(a @ r) \rho^{\prime}$. Hence, also in this case, $\mu=\eta$.

In this way we have proved that any couple of alpha-converted processes have associated the same mapping by basic proofs. In addition, (Alpha) guarantees that any kind of proof associates to alpha-converted processes the same mapping and this concludes our proof.
(ii) We prove the first part by induction on derivations. The second part is a consequence of the first part and (Null).
If $E \vdash P \rightarrow \mu$ is proved by (Null), (Out) or (Imp), $E \vdash o k$ is required.

If $E \vdash P \rightarrow \mu$ is proved by (Sum), $P=Q+R, \mu=\eta \oplus \rho$ and $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$ are the hypothesis and we can use the inductive hypothesis.
If $E \vdash P \rightarrow \mu$ is proved by (Par), the argument goes as in the previous case.
If $E \vdash P \rightarrow \mu$ is proved by (New), then $P=(a @ r) Q$ and the hypothesis is of type $E, a @ r \vdash Q \rightarrow \eta$. The inductive hypothesis gives $E, a @ r \vdash o k$ and this can only be proved by (Env@) from $E \vdash o k$.
If $E \vdash P \rightarrow \mu$ is proved by (Rep), then $P=!Q$ and $E \vdash Q$ is the hypothesis and we can apply the inductive step.
If $E \vdash P \rightarrow \mu$ is proved by (Alpha), we can use the inductive hypothesis again.
Proof (Lemma 2). 1. A simple induction on derivations that involve only (Env $\varepsilon$ ) and (Env@) proves that $E \vdash o k$ iff $E^{\prime} \vdash o k$. For proving our lemma we will proceed with an induction on the derivation of $E \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Null), we have that $P=0$ and due to Theorem $2, \mu=\overline{\mathbb{0}}$. Applying (Null) we obtain $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Out) or (Imp), we have that $P=x \cdot Q$ and $\mu=E_{Q}^{x}$. Because $E_{Q}^{x}=E_{Q}^{\prime x}$ and $\operatorname{dom}(E)=\operatorname{dom}\left(E^{\prime}\right)$, we obtain $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Sum), we have that $P=Q+R, \mu=\eta \oplus \rho$ and the hypothesis are $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$. From the inductive hypothesis we obtain $E^{\prime} \vdash Q \rightarrow \eta$ and $E^{\prime} \vdash R \rightarrow \rho$. Applying (Sum), $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Par) we have that $P=Q \mid R, \mu=\eta_{Q} \otimes_{R}^{E} \rho$ and the hypothesis are $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$. From the inductive hypothesis we obtain $E^{\prime} \vdash^{Q} Q \rightarrow \eta$ and $E^{\prime} \vdash R \rightarrow \underset{\sim}{\rho}$. Further, applying (Par) we get $E^{\prime} \vdash P \rightarrow \eta_{Q} \otimes_{R}^{E^{\prime}} \rho$. But $\eta_{Q} \otimes_{R}^{E} \rho=\eta_{Q} \otimes_{R}^{E^{\prime}} \rho$.

If $E \vdash P \rightarrow \mu$ is proved by (Rep), we have that $P=!Q, \mu=\eta!Q$ and the hypothesis is $E \vdash Q \rightarrow \eta$. Applying the inductive step we get $E^{\prime} \vdash Q \rightarrow \eta$ and (Rep) guarantees that $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (New), we have that $P=(a @ r) Q, \mu=(a @ r) \eta$ and the hypothesis is $E, a @ r \vdash Q \rightarrow \eta$. Hence, $a \notin \operatorname{dom}(E)=\operatorname{dom}\left(E^{\prime}\right)$ and we can apply the inductive hypothesis because $b @ s \in E, a @ r$ iff $b @ s \in E^{\prime}, a @ r$ and obtain $E^{\prime}, a @ r \vdash Q \rightarrow \eta$ where from we get $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Alpha), we have that $P=Q_{\{a / b\}}$ with $a, b \notin$ $f n(P)=f n(Q)$ and the hypothesis is $E \vdash Q \rightarrow \mu$. The inductive hypothesis gives $E^{\prime} \vdash Q \rightarrow \mu$ and because $a, b \notin f n(Q)$, (Alpha) proves $E^{\prime} \vdash P \rightarrow \mu$.
2. Induction on the derivation of $E \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Null), we have that $P=0$ and due to Theorem $2, \mu=\overline{\mathbb{0}}$. Applying (Null) we obtain $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Out) or (Imp), we have that $P=x . Q$ and due to Theorem 2, $\mu=E_{Q}^{x}$. Because $f n(P) \subseteq \operatorname{dom}(E) \subseteq \operatorname{dom}\left(E^{\prime}\right)$ and $E_{Q}^{x}=E_{Q}^{\prime x}$, we obtain $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Sum), we have that $P=Q+R, \mu=\eta \oplus \rho$ and the hypothesis are $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$. From the inductive hypothesis we obtain $E^{\prime} \vdash Q \rightarrow \eta$ and $E^{\prime} \vdash R \rightarrow \rho$. Further, applying (Sum) we get $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Par) we have that $P=Q \mid R, \mu=\eta_{Q} \otimes_{R}^{E} \rho$ and the hypothesis are $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$. From the inductive hypothesis
we obtain $E^{\prime} \vdash Q \rightarrow \eta$ and $E^{\prime} \vdash R \rightarrow \rho$. Further, applying (Par) we get $E^{\prime} \vdash P \rightarrow \eta_{Q} \otimes_{R}^{E^{\prime}} \rho$. But $\eta_{Q} \otimes_{R}^{E} \rho=\eta_{Q} \otimes_{R}^{E^{\prime}} \rho$.

If $E \vdash P \rightarrow \mu$ is proved by (Rep), we have that $P=!Q, \mu=\eta_{!Q}$ and the hypothesis is $E \vdash Q \rightarrow \eta$. Applying the inductive step we get $E^{\prime} \vdash Q \rightarrow \eta$ and (Rep) guarantees that $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Alpha), we have that $P=Q_{\{a / b\}}$ with $a, b \notin$ $f n(P)=f n(Q)$ and the hypothesis is $E \vdash Q \rightarrow \mu$. As before, the inductive hypothesis guarantees that $E^{\prime} \vdash Q \rightarrow \mu$ and because $a, b \notin f n(Q)$, (Alpha) proves that $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (New), we have that $P=(a @ r) Q, \mu=(a @ r) \eta$ and the hypothesis is $E, a @ r \vdash Q \rightarrow \eta$. Hence, $a \notin \operatorname{dom}(E)$. If $a \notin \operatorname{dom}\left(E^{\prime}\right)$, the inductive hypothesis guarantees that $E^{\prime}, a @ r \vdash Q \rightarrow \eta$ where from we get $E^{\prime} \vdash P \rightarrow \mu$. If $a \in \operatorname{dom}\left(E^{\prime}\right)$, let $b \notin \operatorname{dom}\left(E^{\prime}\right) \cup f n(P)$. Because $E, a @ r \vdash Q \rightarrow \eta$ is provable, also $E, b @ r \vdash Q_{\{b / a\}} \rightarrow \eta_{\{b / a\}}$ is provable, where $\eta_{\{b / a\}}$ is the mapping obtained from $\eta$ replacing all the occurrences of $a$ in the definition of $\eta$ (in processes and labels) with $b$. Moreover, to each proof of $E, a @ r \vdash Q \rightarrow \eta$ corresponds a proof of $E, b @ r \vdash Q_{\{b / a\}} \rightarrow \eta_{\{b / a\}}$ that is, from the point of view of our induction, at the same level with the proof of $E, a @ r \vdash Q \rightarrow \eta$. Consequently, we can apply the inductive hypothesis to $E, b @ r \vdash Q_{\{b / a\}} \rightarrow \eta_{\{b / a\}}$ and obtain $E^{\prime}, b @ r \vdash Q_{\{b / a\}} \rightarrow \eta_{\{b / a\}}$. (New) implies $E^{\prime} \vdash(b @ r) Q_{\{b / a\}} \rightarrow(b @ r) \eta_{\{b / a\}}$ and (Alpha) $E^{\prime} \vdash(a @ r) Q \rightarrow(b @ r) \eta_{\{b / a\}}$. To conclude, it is sufficient to verify that $(a @ r) \eta=(b @ r) \eta_{\{b / a\}}$.
3. The proof goes similarly with the proof of the previous case. We use an induction on the derivation of $E \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Null), we have that $P=0$ and $\mu=\overline{0}$. Applying (Null) we obtain $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Out) or (Imp), we have that $P=x . Q$ and $\mu=G_{Q}^{\prime x}$. Because $f n(P) \subseteq \operatorname{dom}(E), f n(P) \cap \operatorname{dom}\left(E \backslash E^{\prime}\right)=\emptyset$ and $E_{Q}^{x}=E_{Q}^{\prime x}$, we obtain $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Sum), we have that $P=Q+R, \mu=\eta \oplus \rho$ and the hypothesis are $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$. From the inductive hypothesis we obtain $E^{\prime} \vdash Q \rightarrow \eta$ and $E^{\prime} \vdash R \rightarrow \rho$. Further, applying (Sum) we get $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Par) we have that $P=Q \mid R, \mu=\eta_{Q} \otimes_{R}^{E} \rho$ and the hypothesis are $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$. From the inductive hypothesis we obtain $E^{\prime} \vdash Q \rightarrow \eta$ and $E^{\prime} \vdash R \rightarrow \rho$. Further, applying (Par) we get $E^{\prime} \vdash P \rightarrow \eta_{Q} \otimes_{R}^{E^{\prime}} \rho$. But $\eta_{Q} \otimes_{R}^{E} \rho=\eta_{Q} \otimes_{R}^{E^{\prime}} \rho$.

If $E \vdash P \rightarrow \mu$ is proved by (Rep), we have that $P=!Q, \mu=\eta_{!Q}$ and the hypothesis is $E \vdash Q \rightarrow \eta$. Applying the inductive step we get $E^{\prime} \vdash Q \rightarrow \eta$ and (Rep) guarantees that $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (Alpha), we have that $P=Q_{\{a / b\}}$ with $a, b \notin$ $f n(P)=f n(Q)$ and the hypothesis is $E \vdash Q \rightarrow \mu$. As before, the inductive hypothesis guarantees that $E^{\prime} \vdash Q \rightarrow \mu$ and because $a, b \notin f n(Q)$, (Alpha) proves that $E^{\prime} \vdash P \rightarrow \mu$.

If $E \vdash P \rightarrow \mu$ is proved by (New), we have that $P=(a @ r) Q, \mu=(a @ r) \eta$ and the hypothesis is $E, a @ r \vdash Q \rightarrow \eta$. Hence, $a \notin \operatorname{dom}(E)$ and because $\operatorname{dom}\left(E^{\prime}\right) \subseteq \operatorname{dom}(E)$, we obtain that $a \notin \operatorname{dom}\left(E^{\prime}\right)$. Because $E, a @ r \subset E^{\prime}, a @ r$ and $\operatorname{dom}\left(\left(E^{\prime}, a @ r\right) \backslash(E, a @ r)\right)=\operatorname{dom}\left(E^{\prime} \backslash E\right)$, we can apply the inductive hypothesis and from $E, a @ r \vdash Q \rightarrow \eta$ we obtain $E^{\prime}, a @ r \vdash Q \rightarrow \eta$ where from we get $E^{\prime} \vdash P \rightarrow \mu$.

Proof (Theorem 5). From $P^{\prime} \equiv P^{\prime \prime}$ we obtain that $f n\left(P^{\prime}\right)=f n\left(P^{\prime \prime}\right)$ and Theorem 2 ensures that $E \vdash P^{\prime} \rightarrow \mu$ implies that there exists a unique $\mu^{\prime}$ such that $E \vdash P^{\prime \prime} \rightarrow \mu^{\prime}$.

We prove now that $E \vdash P^{\prime} \rightarrow \mu$ implies $E \vdash P^{\prime \prime} \rightarrow \mu$. The proof is an induction following the rules of structural congruence presented in Definition 2. Rule I.1: if $P^{\prime}=P \mid Q$ and $P^{\prime \prime}=Q \mid P$. Suppose that $E \vdash P \rightarrow \eta$ and $E \vdash Q \rightarrow \rho$. Then $\mu=\eta_{P} \otimes_{Q}^{E} \rho$ and Lemma 1 guarantees that $E \vdash P^{\prime \prime} \rightarrow \mu$.

Similarly we can treat all the rules of group I.
Rules of group II: As previously, the results derive from the properties of $\oplus$ stated in Lemma 1.
Rules of group III: If $\left(P^{\prime}=P \mid R\right.$ and $\left.P^{\prime \prime}=Q \mid R\right)$, or $\left(P^{\prime}=P+R\right.$ and $\left.P^{\prime \prime}=Q+R\right)$, or $\left(P^{\prime}=x . P\right.$ and $\left.P^{\prime \prime}=x \cdot Q\right)$, or $\left(P^{\prime}=!P\right.$ and $\left.P^{\prime \prime}=!Q\right)$ for $P \equiv Q$, we can apply the inductive hypothesis that guarantees that $E \vdash P \rightarrow \eta$ iff $E \vdash Q \rightarrow \eta$. Further, if $E \vdash R \rightarrow \rho$, we obtain the desired results because $\eta_{P} \otimes_{R}^{E} \rho=\eta_{Q} \otimes_{R}^{E} \rho, \eta \oplus \rho=\eta \oplus \rho, E_{P}^{x}=E_{Q}^{x}$ and $\mu_{!P}=\mu_{!Q}$.
If $P^{\prime}=(a @ r) \stackrel{P}{P}$ and $P^{\prime \prime}=(a @ r) Q$, we have two subcases.
Subcase 1: $a \notin \operatorname{dom}(E)$. Suppose that $E, a @ r \vdash P \rightarrow \eta$. From the inductive hypothesis we obtain that $E, a @ r \vdash Q \rightarrow \eta$. Further, rule (New) proves that $\mu=(a @ r) \eta$ and $E \vdash(a @ r) Q \rightarrow \mu$.

Subcase 2: $a \in \operatorname{dom}(E)$. Let $b \in \mathcal{N} \backslash \operatorname{dom}(E)$. Suppose that $E, b @ r \vdash$ $P_{\{b / a\}} \rightarrow \eta$. Then, (New) implies $E \vdash(b @ r) P_{\{b / a\}} \rightarrow(b @ r) \eta$ and (Alpha) proves $E \vdash(a @ r) P \rightarrow(b @ r) \eta$. Hence, $\mu=(b @ r) \eta$. On the other hand, the inductive hypothesis implies $E, b @ r \vdash Q_{\{b / a\}} \rightarrow \eta$, (New) proves $E \vdash(b @ r) Q_{\{b / a\}} \rightarrow$ $(b @ r) \eta$ and (Alpha) implies $E \vdash(a @ r) Q \rightarrow(b @ r) \eta$.
Rule IV.1: If $P^{\prime}=(a @ r)(b @ s) P$ and $P^{\prime \prime}=(b @ s)(a @ r) P$. Let $c, d \in \mathcal{N} \backslash$ $\operatorname{dom}(E)$. Suppose that $E ; c @ r ; d @ s \vdash P_{\{c / a, d / b\}} \rightarrow \eta$. Applying twice (New) we obtain $E \vdash(c @ r)(d @ s) P_{\{c / a, d / b\}} \rightarrow(c @ r)(d @ s) \eta$ and applying twice (Alpha) we get $E \vdash(a @ r)(b @ s) P \rightarrow(c @ r)(d @ s) \eta$. Hence, $\mu=(c @ r)(d @ s) \eta$. On the other hand, Lemma 2.1 guarantees that $E ; c @ r ; d @ s \vdash P_{\{c / a, d / b\}} \rightarrow \eta$ implies $E ; d @ s ; c @ r \vdash P_{\{c / a, d / b\}} \rightarrow \eta$ and, as before, we eventually obtain $E \vdash$ $(b @ s)(a @ r) P \rightarrow(d @ s)(c @ r) \eta$. Now it is suficient to verify that $(d @ s)(c @ r) \eta=$ $(c @ r)(d @ s) \eta$.
Rule IV.2: If $P^{\prime}=(a @ r) 0$ and $P^{\prime \prime}=0$. In this case it is sufficient to notice that $(a @ r) \overline{0}=\overline{0}$.
Rule IV.3: If $P^{\prime}=(a @ r)(P \mid Q)$ and $P^{\prime \prime}=P \mid(a @ r) Q$, where $a \notin f n(P)$. Let $b \in$ $\mathcal{N} \backslash(\operatorname{dom}(E) \cup f n(P))$. Suppose that $E, b @ r \vdash P \rightarrow \eta$ and $E, b @ r \vdash Q_{\{b / a\}} \rightarrow \rho$. Observe that because $a \notin f n(P)$, we also have $E, b @ r \vdash P_{\{b / a\}} \rightarrow \eta$. Further we obtain

$$
E, b @ r \vdash(P \mid Q)_{\{b / a\}} \rightarrow \eta_{P_{\{b / a\}}} \otimes_{Q_{\{b / a\}}}^{E, b @ r} \rho \text { and }
$$

$$
E \vdash(b @ r)\left((P \mid Q)_{\{b / a\}}\right) \rightarrow(b @ r)\left(\eta_{P_{\{b / a\}}} \otimes_{Q_{\{b / a\}}}^{E, b @ r} \rho\right) .
$$

Now we apply (Alpha) and obtain

$$
E \vdash(a @ r)(P \mid Q) \rightarrow(b @ r)\left(\eta_{P} \otimes_{Q_{\{b / a\}}}^{E, b @ r} \rho\right)
$$

On the other hand, because $b \notin f n(P)$, from $E, b @ r \vdash P \rightarrow \eta$ Lemma 2.2 proves $E \vdash P \rightarrow \eta$ and from $E, b @ r \vdash Q_{\{b / a\}} \rightarrow \rho$ we obtain, applying (New), $E \vdash(b @ r) Q_{\{b / a\}} \rightarrow(b @ r) \rho$. And further,

$$
E \vdash P \mid(b @ r) Q_{\{b / a\}} \rightarrow \eta_{P} \otimes_{(b @ r) Q_{\{b / a\}}}^{E}(b @ r) \rho .
$$

Applying (alpha) we obtain

$$
E \vdash P \mid(a @ r) Q \rightarrow \eta_{P} \otimes_{(b @ r) Q_{\{b / a\}}}^{E}(b @ r) \rho .
$$

A simple verification based on the observation that (if for all $R \in \mathcal{R}, b \notin f n(R)$, then $(b @ r) \mathcal{R}=\mathcal{R})$ proves that

$$
(b @ r)\left(\eta_{P} \otimes_{Q_{\{b / a\}}}^{E, b @ r} \rho\right)=\eta_{P} \otimes_{(b @ r) Q_{\{b / a\}}}^{E}(b @ r) \rho
$$

Similarly can be proved that case $P^{\prime}=(a @ r)(P+Q)$ and $P^{\prime \prime}=P+(a @ r) Q$, where $a \notin f n(P)$.
Rules of group V: By a simple verification one can prove that $\overline{\mathbb{D}}_{!0}=\overline{\mathbb{O}}$. For the second rule, observe that if $E \vdash P \rightarrow \eta$ and $E \vdash Q \rightarrow \rho$, then $E \vdash!(P \mid Q) \rightarrow$ $\left(\eta_{P} \otimes_{Q}^{E} \rho\right)_{!(P \mid Q)}$ and $E \vdash!P \mid!Q \rightarrow \eta_{!Q \mid P} \otimes_{!P \mid Q}^{E} \rho$. And a simple verification proves that

$$
\left(\eta_{P} \otimes_{Q}^{E} \rho\right)_{!(P \mid Q)}=\eta_{!Q \mid P} \otimes_{!P \mid Q}^{E} \rho .
$$

Rules of group VI: These rules are a direct consequence of (Alpha).
Proof (Theorem 5). 1. Prefix: For any $C \in \Pi(\sim), P \in C$ iff $Q \in C$. This entails that for any $E \in \mathbb{E}$ with $f n(x . P) \cup f n(x . Q) \subseteq \operatorname{dom}(E)$ and any $\alpha \in \mathbb{A}^{+}$, $E_{P}^{x}(\alpha)(C)=E_{Q}^{x}(\alpha)(C)$.
2. Choice: We can suppose, without loosing generality, that $E \vdash P \rightarrow \mu$, $E \vdash Q \rightarrow \eta$ and $E \vdash R \rightarrow \rho$ (the other cases are trivially true). Then, $E \vdash$ $P+R \rightarrow \mu \oplus \rho$ and $E \vdash Q+R \rightarrow \eta \oplus \rho$. Let $C \in \Pi(\sim)$ and $\alpha \in \mathbb{A}^{+}$. Because $P \sim Q, \mu(\alpha)(C)=\eta(\alpha)(C)$ implying $\mu(\alpha)(C)+\rho(\alpha)(C)=\eta(\alpha)(C)+\rho(\alpha)(C)$. This means that $(\mu \oplus \rho)(\alpha)(C)=(\eta \oplus \rho)(\alpha)(C)$.
3. Fresh name quantification: Let $E \in \mathbb{E}$ and $b \notin \operatorname{dom}(E) \cup f n(P) \cup f n(Q)$. Observe that from $P \sim Q$, following an observation that we used also in the proof of Lemma 2 concerning the relation between a mapping $\eta$ its correspondent $\eta_{\{b / a\}}$, we derive $P_{\{b / a\}} \sim Q_{\{b / a\}}$. Suppose that $E, b @ r \vdash P_{\{b / a\}} \rightarrow \mu$ and $E, b @ r \vdash Q_{\{b / a\}} \rightarrow \eta$. Applying (New) we obtain $E \vdash(b @ r) P_{\{b / a\}} \rightarrow(b @ r) \mu$ and $E \vdash(b @ r) Q_{\{b / a\}} \rightarrow(b @ r) \eta$. (Alpha) implies $E \vdash(a @ r) P \rightarrow(b @ r) \mu$ and $E \vdash(a @ r) Q \rightarrow(b @ r) \eta$. From $P_{\{b / a\}} \sim Q_{\{b / a\}}$ we obtain that for any $\alpha \in \mathbb{A}^{+}$ and any $C \in \Pi(\sim), \mu(\alpha)(C)=\eta(\alpha)(C)$. to conclude the proof it is sufficient to verify that $(b @ r) \mu(\alpha)(C)=(b @ r) \eta(\alpha)(C)$.
4. Parallel composition: For the beginning we consider the processes that, to all syntactic levels, contain no subprocess form the class $0 \equiv$ in a parallel composition. Let's call them processes with non-trivial forms. We will first prove the lemma for processes with non-trivial forms.

For arbitrary $n \in \mathbb{N}$, let $\mathbb{S}^{n}$ be the set of process terms with non-trivial forms and no more than $n$ occurrences of the operator "". Let $\sim^{n} \subseteq \mathbb{S}^{n} \times \mathbb{S}^{n}$ be the largest rate-bisimulation defined on $\mathbb{S}^{n}$. We define $\approx^{n} \in \mathbb{S}^{n} \times \mathbb{S}^{n}$ by

$$
\approx^{n}=\sim^{n-1} \cup
$$

$$
\left\{\left(P_{1}|\ldots| P_{k}, Q_{1}|\ldots| Q_{k}\right),\left(P_{1}+\ldots P_{k}, Q_{1}+\ldots Q_{k}\right) \text { for } P_{i} \sim^{n-1} Q_{i}, i=1 . . k, k \leq n\right\}
$$

We show, by induction on $n$, that $\approx^{n}$ is a rate-bisimulation, i.e. that $\approx^{n} \subseteq \sim^{n}$.
Suppose that $P \approx^{n} Q$. We need to prove that if $E \vdash P \rightarrow \mu$ and $E \vdash Q \rightarrow \eta$, then for any $\alpha \in \mathbb{A}^{+}$and any $C \in \Pi\left(\approx^{n}\right), \mu(\alpha)(C)=\eta(\alpha)(C)$.

Observe that, from the way we construct $\approx^{n}$, there are three possibilities: either $P \sim^{n-1} Q$, or $P=P_{1}+\ldots P_{k}$ and $Q=Q_{1}+\ldots Q_{k}$, or $P=P_{1}|\ldots| P_{k}$ and $Q=Q_{1}|\ldots| Q_{k}$, for $k \leq n$, with $P_{i} \sim^{n-1} Q_{i}$ for each $i=1 . . k$. In the first two cases, using also the case of choice operator that we have already proved, it is trivial to verify that $\mu(\alpha)(C)=\eta(\alpha)(C)$.

To prove the last case observe for the beginning that because $\sim^{n-1} \subseteq \sim^{n}$, the inductive hypothesis guarantees that for each $i=1 . . k$,
$P_{1}|\ldots| P_{i-1}\left|P_{i+1}\right| \ldots\left|P_{k} \approx^{n-1} Q_{1}\right| \ldots\left|Q_{i-1}\right| Q_{i+1}|\ldots| Q_{k}$ and consequently that $P_{1}|\ldots| P_{i-1}\left|P_{i+1}\right| \ldots\left|P_{k} \sim^{n-1} Q_{1}\right| \ldots\left|Q_{i-1}\right| Q_{i+1}|\ldots| Q_{k}$.

Suppose that $E \vdash P_{i} \rightarrow \mu_{i}$ and $E \vdash Q_{i} \rightarrow \eta_{i}$ for all $i=1 . . k$. Then,

$$
\begin{aligned}
& \mu=\mu_{1 P_{1}} \otimes_{P_{2}|\ldots| P_{k}}^{E}\left(\mu_{2 P_{2}} \otimes_{P_{3}|\ldots| P_{k}}^{E}\left(\ldots\left(\mu_{k-1 P_{k-1}} \otimes_{P_{k}}^{E} \mu_{k}\right) \ldots\right),\right. \\
& \eta=\eta_{Q_{1}} \otimes_{Q_{2}|\ldots| Q_{k}}^{E}\left(\eta_{2} Q_{2} \otimes_{Q_{3}|\ldots| Q_{k}}^{E}\left(\ldots\left(\eta_{k-1} Q_{k-1} \otimes_{Q_{k}}^{E} \eta_{k}\right) \ldots\right),\right.
\end{aligned}
$$

Consider an arbitrary $\alpha \in \mathbb{A}$. Then,

$$
\begin{aligned}
& \mu(\alpha)(C)=\sum_{i=1 . . k} \mu_{i}(\alpha)\left(C_{P_{1}|\ldots| P_{i-1}\left|P_{i+1}\right| \ldots \mid P_{k}}\right), \\
& \eta(\alpha)(C)=\sum_{i=1 . . k} \eta_{i}(\alpha)\left(C_{Q_{1}|\ldots| Q_{i-1}\left|Q_{i+1}\right| \ldots \mid Q_{k}}\right) .
\end{aligned}
$$

Because $C \in \Pi\left(\approx^{n}\right), C_{P_{1}|\ldots| P_{i-1}\left|P_{i+1}\right| \ldots \mid P_{k}}$ and $C_{Q_{1}|\ldots| Q_{i-1}\left|Q_{i+1}\right| \ldots \mid Q_{k}}$ contain only processes with at most $n-1$ occurrences of $\mid$, for any $i$. And because $P_{1}|\ldots| P_{i-1}\left|P_{i+1}\right| \ldots\left|P_{k} \sim^{n-1} Q_{1}\right| \ldots\left|Q_{i-1}\right| Q_{i+1}|\ldots| Q_{k}$, we obtain

$$
C_{P_{1}|\ldots| P_{i-1}\left|P_{i+1}\right| \ldots \mid P_{k}}=C_{Q_{1}|\ldots| Q_{i-1}\left|Q_{i+1}\right| \ldots \mid Q_{k}} \in \Pi\left(\sim^{n-1}\right) .
$$

Further, using the fact that $\sim^{n-1}$ is a rate bisimulation, we obtain

$$
\mu(\alpha)\left(C_{P_{1}|\ldots| P_{i-1}\left|P_{i+1}\right| \ldots \mid P_{k}}\right)=\eta(\alpha)\left(C_{Q_{1}|\ldots| Q_{i-1}\left|Q_{i+1}\right| \ldots \mid Q_{k}}\right)
$$

that implies $\mu(\alpha)(C)=\eta(\alpha)(C)$.

A similar argument proves the case $\alpha=\tau$. Consequently, $\approx^{n}$ is a ratebisimulation.

Returning to our lemma, suppose that $P$ and $Q$ are two processes with nontrivial forms such that $P \sim Q$. Then, there exists $n \in \mathbb{N}$ such that $P \sim^{n} Q$. Suppose that $R \in \mathbb{S}^{m}$ for some $m \in \mathbb{N}$. Then $P \sim^{m+n-1} Q$ and $R \sim^{m+n-1} R$ implying $P\left|R \approx^{m+n} Q\right| R$. Because $\approx^{m+n}$ is a rate-bisimulation, we obtain that $P|R \sim Q| R$.

If $P, Q$ or $R$ (or some of them) have "trivial forms", then there exist $P^{\prime} \equiv P$, $Q^{\prime} \equiv Q$ and $R^{\prime} \equiv R$ with non-trivial forms. And because the bisimulation is an equivalence that extends the structural congruence, we obtain the desired result also for the general case.
5. Replication: We use the same proof strategy as for the parallel composition. We say that a process is in canonic form if it contains no parallel composition of replicated subprocesses and no replicated process from the class $0 \equiv$. In other words, $!(P \mid Q)$ is in canonic form while $!P \mid!Q$ and $!(P \mid Q) \mid!!0$ are not; using the structural congruence rules, we can associate to each process $P$ a structural congruent process with a canonic form called a canonic representative for $P$. Notice also that all the canonic representatives of a given process have the same number of occurrences of the operator "!". Let $\mathbb{S}_{*}$ be the set of process terms with canonic form. Observe that because structural congruence is a subset of bisimulation, it is sufficient to prove our lemma only for processes in $\mathbb{S}_{*}$.

As before, let $\mathbb{S}_{*}^{n}$ be the set of processes (in canonic form) with no more than $n$ occurrences of the operator "!". Let $\sim^{n}$ be the stochastic bisimulation on $\mathbb{S}_{*}^{n}$ and $\approx^{n} \subseteq \mathbb{S}_{*}^{n} \times \mathbb{S}_{*}^{n}$ defined by

$$
\approx^{n}=\sim^{n-1} \cup\left\{(!P,!Q) \mid P \sim^{n-1} Q\right\}
$$

We firstly show, inductively on $n$, that $\approx^{n}$ is a rate-bisimulation. Consider two arbitrary processes $P$ and $Q$ such that $P \approx^{n} Q$. We prove that if $E \vdash P \rightarrow \mu$ and $E \vdash Q \rightarrow \eta$, then for arbitrary $\alpha \in \mathbb{A}^{+}$and $C \in \Pi\left(\approx^{n}\right), \mu(\alpha)(C)=\eta(\alpha)(C)$.

Observe that if $P \approx^{n} Q$, then either $P \sim^{n-1} Q$, or $P \equiv!R$ and $Q \equiv!S$ with $R \sim^{n-1} S$. In the first case the equality is trivially true. In the other case, suppose that $E \vdash R \rightarrow \mu^{\prime}$ and $E \vdash S \rightarrow \eta^{\prime}$. Then, $\mu=\mu_{!R}^{\prime}$ and $\eta=\eta_{!S}^{\prime}$. We have

$$
\mu(\alpha)(C)=\mu^{\prime}(\alpha)\left(C_{!R}\right), \quad \eta(\alpha)(C)=\eta^{\prime}(\alpha)\left(C_{!S}\right)
$$

We prove that $C_{!R}=C_{!S}$. Let $U \in C_{!R}$. Then, $U \mid!R \in C$ and from the construction of $C \in \Pi\left(\approx^{n}\right)$, we obtain that there exists $T \in \mathbb{S}_{*}^{n-1}$ such that $U=!T$. Because $!R \mid!T \in C,!(R \mid T) \in C$. Now, from $R \sim^{n-1} S$ we obtain $R \sim S$ and because $T \sim T$, the case of parallel operator that we have proved guarantees that $R|T \sim S| T$. But the canonic representatives $V, W$ of $R \mid T$ and $S \mid T$ respectively are in $\mathbb{S}_{*}^{n-1}$ meaning that $V \sim^{n-1} W$. The construction of $\approx^{n}$ guarantees further that $!V \approx^{n}!W$ and because $W \equiv S \mid T$ we obtain ! $(S \mid T) \in C$ and $U \equiv!T \in C_{!S}$.

Because $C_{!R}=C_{!S}$ and $\mu^{\prime}(\alpha)\left(C_{!R}\right)=\eta^{\prime}(\alpha)\left(C_{!S}\right)$ (this is implied by $R \sim^{n-1}$ $S)$, then $\mu(\alpha)(C)=\eta(\alpha)(C)$.
